The effects of growth temperature and annealing on the physical properties of  $\text{Zn}_3\text{Sn}_2\text{O}_7$  thin films were investigated in this work. The  $\text{Zn}_3\text{Sn}_2\text{O}_7$  thin films were deposited on glass substrates by radio frequency (rf) magnetron sputtering. It is found that the films are amorphous regardless of the growth temperature. The film grown at room temperature shows the highest mobility of  $8.1 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$  and the lowest carrier concentration of  $2.0 \times 10^{15} \text{ cm}^{-3}$ . The highest carrier concentration of  $1.6 \times 10^{19} \text{ cm}^{-3}$  is obtained at the growth temperature of  $250^\circ\text{C}$ . Annealing treatment of the  $\text{Zn}_3\text{Sn}_2\text{O}_7$  thin films resulted in increases of carrier concentration and mobility. The average transmittance of the as-deposited and annealed films reaches 80%. By using a  $\text{Zn}_3\text{Sn}_2\text{O}_7$  thin film as the channel and a  $\text{Ta}_2\text{O}_5$  thin film as the insulating layer, we fabricated transparent  $\text{Zn}_3\text{Sn}_2\text{O}_7$  thin-film transistors with field-effect mobility of  $21.2 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$ , on/off current ratio of  $10^5$ , threshold voltage of 0.8 V, and subthreshold swing of 0.8 V/decade.

## INTRODUCTION

Thin-film transistors (TFTs) have been widely used in many fields, such as flat-panel displays, computers, and sensors. TFTs based on transparent conducting oxides (TCOs) such as  $\text{ZnO}$ ,<sup>1</sup>  $\text{SnO}_2$ ,<sup>2</sup> and multicomponent alloy oxides such as  $\text{Zn-Mg-O}$ ,<sup>3</sup>  $\text{Zn-Sn-O}$ ,<sup>4</sup>  $\text{Zn-In-O}$ ,<sup>5</sup> and  $\text{In-Ga-Zn-O}$ <sup>6</sup> have attracted much attention in recent years because of their high electron mobility and high optical transparency in the visible region compared with amorphous silicon. Among these oxides,  $\text{Zn}_3\text{Sn}_2\text{O}_7$  is a promising channel material for high-performance TFTs. The advantages of  $\text{Zn}_3\text{Sn}_2\text{O}_7$  include its low sensitivity to visible light, physical robustness, and extremely high resistance to scratching,<sup>7</sup> as well as the abundance of Zn and Sn on Earth.<sup>7</sup>  $\text{Zn}_3\text{Sn}_2\text{O}_7$  thin films have been realized by many methods, such as spray pyrolysis, the sol-gel method, pulsed

laser deposition, sputtering, and filtered vacuum arc deposition. In this work,  $\text{Zn}_3\text{Sn}_2\text{O}_7$  thin films were deposited by rf magnetron sputtering using an alloy target. The effects of growth temperature and annealing on the structural, electrical, and optical properties of  $\text{Zn}_3\text{Sn}_2\text{O}_7$  thin films were investigated. We also fabricated fully transparent  $\text{Zn}_3\text{Sn}_2\text{O}_7$  TFT devices on glass substrates using a  $\text{Zn}_3\text{Sn}_2\text{O}_7$  film as the channel and a  $\text{Ta}_2\text{O}_5$  film as the insulating layer. The TFT devices exhibit good saturation characteristics and gate voltage control.

## EXPERIMENTAL PROCEDURES

### $\text{Zn}_3\text{Sn}_2\text{O}_7$ Film

$\text{Zn}_3\text{Sn}_2\text{O}_7$  thin films were deposited on glass substrates by rf magnetron sputtering using an alloy target of 50 wt.%  $\text{ZnO}$ -50 wt.%  $\text{SnO}_2$ . High-purity (99.999%) argon was used as sputtering gas in the deposition process. The flow rate of Ar gas was 20 sccm, and the working pressure was 3.0 Pa. The target power was fixed at 300 W. The glass
