## Abstract

Let G = (V, E) be a simple and undirected graph. For some real number  $\alpha$  with  $0 < \alpha \leq 1$ , a set  $D \subseteq V$  is called an  $\alpha$ -dominating set in G if every vertex v outside D has at least  $\alpha \cdot d_v$  neighbor(s) in S where  $d_v$  is the degree of v. The cardinality of a minimum  $\alpha$ -dominating set in a graph G is called the  $\alpha$ -domination number of G and denoted by  $\gamma_{\alpha}(G)$ . In this paper, we introduce a generalization of  $\alpha$ -dominating set, that we call it  $f_{deg}$ -dominating set. Given a function  $f_{deg}$  where  $f_{deg}$  is as  $f_{deg} : \mathbb{N} \to \mathbb{R}$  where  $\mathbb{N} = \{1, 2, 3, \ldots\}$ , and  $f_{deg}$  may not be an integer-value function. A set  $D \subseteq V$  is called an  $f_{deg}$ -dominating set in G if for every vertex v outside D,  $|N(v) \cap D| \geq f_{deg}(d_v)$ . In this paper, for this new concept, we will present some results on the its NP-completeness, APX-completeness and inapproximability.

## 1 Introduction

Let G = (V, E) be an undirected and simple graph. A set  $D \subseteq V$  is called a *dominating* set if every vertex outside D has at least one neighbor in D. The cardinality of a minimum dominating set is called the *domination number* of G denoted by  $\gamma(G)$ . In 2000, Dunbar et al. [5], introduced the concept of  $\alpha$ -domination. Let  $\alpha$  be a real number with  $0 < \alpha \leq 1$ . A set  $D \subseteq V$  is called an  $\alpha$ -dominating set in G if for every vertex v outside D,  $|N(v) \cap D| \geq \alpha \times d_v$  where N(v) is the set of all neighbors of v in G, and  $d_v := |N(v)|$  is the degree of v. Also, let k be a real number with  $k \geq 1$ . A set  $D \subseteq V$  is called a k-dominating set in G if for every vertex v outside a k-dominating set in G if for every vertex  $v \in V$  is called a k-dominating set in G if for every vertex  $v \in V$  is called a k-dominating set in G if for every vertex  $v \in V$  is called a k-dominating set in G if for every vertex  $v \in V$  is called a k-dominating set in G if for every vertex  $v \in V$  is called a k-dominating set in G if for every vertex  $v \in V$  is called a k-dominating set in G if for every vertex  $v \in V$  is called a k-dominating set in G if for every vertex  $v \in V$  outside D,  $|N(v) \cap D| \geq k$ .

Now consider the definition of  $\alpha$ -dominating. One generalization of this concept is that instead of having at least  $\alpha \times d_v$  neighbors in D for each vertex  $v \notin D$ , we have at least  $f(d_v)$  neighbors in D, for some special function f. By selecting  $f(x) = \alpha x$ , the definition match the  $\alpha$ -dominating. It seems that this generalization is much near to the reality. Hence, in this paper, we define the  $f_{deg}$ -dominating set. Given a function  $f_{deg}$ where  $f_{deg}$  is as  $f_{deg} : \mathbb{N} \to \mathbb{R}$  where  $\mathbb{N} = \{1, 2, 3, \ldots\}$ , and  $f_{deg}$  may not be an integervalue function. A set  $D \subseteq V$  is called an  $f_{deg}$ -dominating set in G if for every vertex voutside D,  $|N(v) \cap D| \geq f_{deg}(d_v)$ . In this paper, we consider the graphs with no isolated vertices. We can easily extend the results for the graphs with isolated vertices. In this
